

System Overview

A game that allows the user to play video games while also learning things that can be used for school and for real-life scenarios. The following system elements are going to be used for this project:

- **UI (User Interface):** A friendly UI is needed for a great experience for the user.
- **Systems Layer:** Allows for I/O to be implemented.
- **Data Structures:** Allows for creating, modifying, and storing data for the user's convenience.
- **Service Integration:** Things like notifications or reminders to notify the user.

UI (User Interface): A user interface must be friendly to the user. With interface mostly easy to read, less cluttering with the background, and easy to navigate. Additionally, users may want to adjust their settings to their preferred default. Many games have their own settings (like turning off background music). Additionally, activity tracking is key to improve the users experience with the game.

Systems Layer: This is the core component of the system overview. It handles every I/O interaction. For instance, a game loading may need multiple threads for downloading resources for the game and showing the loading screen for the user. We don't want the user to think that the app is frozen. That is why we need to keep the system's layer hidden. Any answers that the user will enter has to be checked by the system to see if it is correct or not.

Data Structures: It is responsible for creating, managing, and modifying data. This is crucial if the user for instance wants to create their own **Hot War**.

Service Integration: Things like notifications or reminders to notify the user to study for this material or move on to the next material.
